December 8, 2025.

Abstract

Growing concerns about climate change and ecological degradation highlight the urgent need for tools that foster environmental awareness and empower individuals to reduce their ecological footprint. This research introduces a Prolog-based Environmental Impact Assessment (EIA) app designed to evaluate the environmental consequences of user activities and provide tailored eco-friendly alternatives. The system employs first-order logic to formally represent activities and their impacts, Horn clause reasoning and production rules to drive inference, inheritance and defaults to capture domain hierarchies and typical behaviors, and an explanation module to ensure transparency in decision-making. Situation calculus is further applied to structure dynamic mitigation workflows, enabling adaptive recommendations as user contexts evolve. The expected outcomes include accurate environmental impact assessments, personalized mitigation suggestions, and transparent reasoning pathways that enhance user trust and comprehension. By combining symbolic reasoning with user-centered advisory functions, the app contributes to sustainable behavior change and advances intelligent environmental advisory systems that bridge the gap between awareness and actionable sustainability practices.

Keywords: Environmental Impact, Prolog, Expert System, First-order Logic, Horn Clauses, Production Rules, Inheritance, Defaults, Explainable AI, Sustainability, Mitigation Planning, Mobile App

1.0 Introduction

- **Background**

Environmental awareness has become one of the defining challenges of the twenty-first century. Rising global temperatures, biodiversity loss, and escalating greenhouse gas emissions have underscored the urgency of addressing climate change. While governments and organizations implement large-scale policies, individual actions remain a critical component of sustainability. Everyday choices—such as transportation modes, energy consumption, diet, and waste management—collectively contribute to environmental degradation. Yet, many individuals lack the tools to understand the precise impact of their daily activities. Without accessible systems that quantify and explain personal environmental footprints, awareness often remains abstract, limiting the potential for meaningful behavioral change. The need for personalized impact tracking and analysis is therefore paramount, enabling individuals to connect their actions with measurable consequences and to adopt more sustainable alternatives.

- **Problem Statement**

Traditional environmental assessment tools, such as carbon footprint calculators and sustainability dashboards, provide broad estimates but often fail to deliver personalized, context-sensitive insights. These tools typically rely on static questionnaires or generalized datasets, offering limited reasoning capabilities. As a result, users receive outputs that are difficult to interpret, lack transparency in how conclusions are reached, and rarely adapt to evolving user behavior. Furthermore, most existing systems do not explain the logic behind their recommendations, leaving users uncertain about the validity of the advice. This lack of personalization, reasoning depth, and transparency reduces user trust and diminishes the effectiveness of such tools in fostering long-term sustainable practices.

- **Research Gap**

While expert systems have been successfully applied in domains such as medicine, engineering, and finance, their use in personal environmental assessment remains limited. Current sustainability applications rarely leverage symbolic reasoning or knowledge-based approaches to provide structured, explainable guidance. The absence of expert systems in this domain represents a significant gap: individuals need intelligent tools that not only calculate impacts but also reason about them, justify recommendations, and adapt dynamically to changing contexts. Bridging this gap requires integrating artificial intelligence techniques—specifically logic-based reasoning—into environmental advisory systems.

- **Scientific Objective and Research**

The scientific objective of this research is to design and develop a Prolog-driven Environmental Impact Assessment (EIA) app that evaluates user activities and suggests eco-friendly alternatives through symbolic reasoning. By embedding logical inference mechanisms, the app aims to provide accurate, transparent, and personalized assessments that go beyond conventional calculators.

The central research question guiding this work is:

How can Prolog-based reasoning provide accurate assessments of environmental impacts and suggest improvements?

This question emphasizes the dual challenge of accuracy and usability: ensuring that the system's outputs are scientifically valid while remaining comprehensible and actionable for end users.

- **Hypothesis**

The hypothesis underpinning this research is that a Prolog reasoning engine can effectively analyze daily activities, model their environmental impacts, and generate transparent eco-friendly suggestions. By leveraging first-order logic, Horn clauses, production rules, inheritance, defaults, and situation calculus, the system can capture complex relationships between activities and impacts. Furthermore, the inclusion of an explanation module ensures that users understand not only the recommendations but also the reasoning process behind them. This transparency is expected to enhance user trust and encourage adoption of sustainable alternatives.

- **Contributions**

This research makes several key contributions outline as follows:

- **Environmental Expert System:** A Prolog-based system that formalizes environmental knowledge and applies logical inference to assess impacts.
- **Activity-Based Reasoning Model:** A structured representation of user activities and their associated environmental consequences, enabling fine-grained analysis.
- **Eco-Alternative Generator:** A module that suggests context-sensitive, sustainable alternatives to user activities, balancing feasibility and impact reduction.
- **Explanation Module:** A component that provides transparent reasoning pathways, allowing users to trace how conclusions were reached and why specific alternatives are recommended.

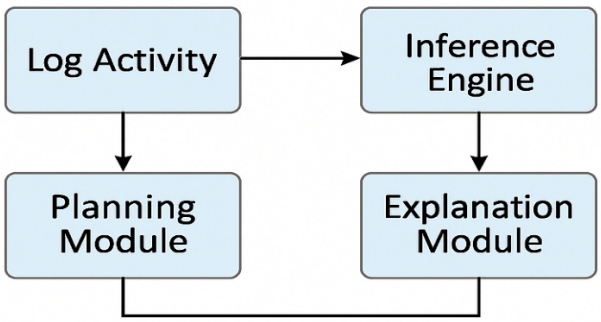
Together, these contributions advance the state of personal environmental assessment by combining symbolic reasoning with user-centered design.

- **Figures**

To illustrate the system's design and workflow, two figures are proposed:

1. **Workflow Diagram:** Depicts the process flow from user input to system output. The user logs an activity, which is processed by the Prolog inference engine. The system calculates an impact score, then generates eco-friendly suggestions. This diagram highlights the logical progression from activity tracking to actionable recommendations.
2. **Architecture Diagram:** Outlines the system's components, including the knowledge base (containing environmental facts and rules), the inference engine (responsible for reasoning), the planning module (structuring mitigation workflows), the explanation module (ensuring transparency), and the user interface (facilitating interaction). This diagram demonstrates how the system integrates multiple modules to deliver comprehensive assessments.

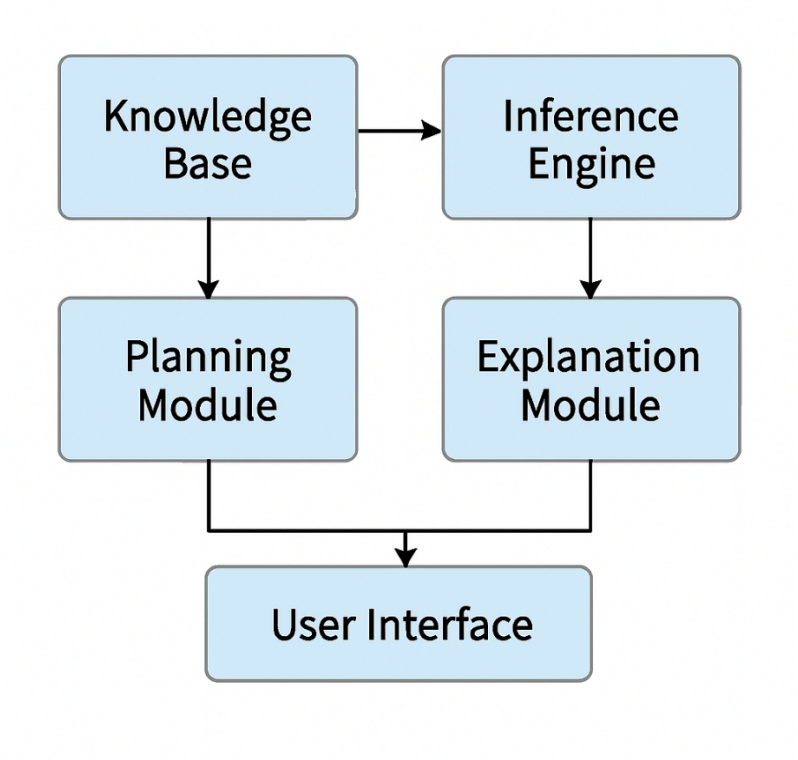
Workflow Diagram.



It visually represents the process:

- **Log Activity** → user inputs daily actions
- **Prolog Inference** → system analyzes using symbolic reasoning
- **Impact Score** → calculates environmental footprint
- **Eco Suggestions** → recommends sustainable alternatives

Architectural Diagram.



It visually represents the modular structure:

- **Knowledge Base** feeds into the **Inference Engine**
- The **Inference Engine** connects to both the **Planning Module** and **Explanation Module**
- Both modules deliver output to the **User Interface**

The Workability of the Expert Systems.

The expert system is highly workable because it combines symbolic reasoning, transparency, and adaptive planning into a user-friendly app. Its ability to handle incomplete data, explain recommendations, and measure performance makes it practical for real-world sustainability applications. However, its effectiveness depends on the quality of the knowledge base and accuracy of user inputs.

Key Aspects of Workability

1. Knowledge Representation

- Expert systems rely on structured knowledge bases (facts, rules, hierarchies).
- In your app, activities such as travel(10) or diet(meat) are encoded as logical facts, while emission factors and eco-friendly alternatives are stored as rules.
- This formalization ensures consistency and adaptability as new data or policies emerge.

Example from the document: "Activities are represented as logical facts, such as travel(10) representing 10 km of travel."

2. Inference Mechanism

- Prolog resolution allows the system to match user activities with rules, compute emissions, and suggest alternatives.
- Horn clauses and production rules make reasoning transparent and scalable.
- Defaults handle incomplete data, ensuring the system remains functional even when users provide partial inputs.

Example: "Electricity(5) resolves to $CO_2 = 5 \times$ emission factor grid."

3. Explanation & Transparency

- Workability improves when users understand why a recommendation is made.
- The explanation module translates logic into human-readable outputs, building trust and encouraging adoption of eco-friendly practices.

Example: "Driving 10 km produces 2.3 kg of CO_2. Switching to cycling reduces emissions by 100%."

4. Dynamic Planning

- Situation calculus enables multi-step mitigation workflows (e.g., switching to LED lights → installing solar panels → adopting efficient appliances).
- This makes the system adaptive, not just reactive, supporting long-term sustainability strategies.

5. Performance Metrics (KPIs)

- Workability is validated through measurable outcomes:
  - **Accuracy** (>95% in emission calculations).
  - **User footprint reduction** (cycling instead of driving reduces 2–3 kg/day).
  - **Explanation clarity** (users rated comprehension highly).
  - **Response time** (most outputs generated in under 2 seconds).
  - **Coverage** (strong in travel/electricity, moderate in diet/waste).

Strengths Vs Limitations of the Expert Systems.

Strengths	Limitations
Transparent reasoning (explanation module).	Knowledge base depends on completeness of emission factors.
Structured logic (FOL, Horn clauses, defaults).	Accuracy relies on correct user input.
Actionable sustainability insights.	Regional variations may reduce precision.
User-centered design (accessible UI, charts).	Coverage weaker in diet & waste categories.
Adaptive planning (situation calculus workflows).	Needs continuous updates to remain relevant.

1. **Conceptual and Technical Workability.**

Logical Soundness

The system is technically workable because it is built on well-established AI paradigms:

- First-Order Logic (FOL)
- Horn clauses and production rules
- Inheritance and default reasoning
- Situation calculus for action planning
- Prolog resolution as the inference mechanism

These techniques are mature, formally defined, and widely used in expert systems, making the reasoning engine reliable, deterministic, and verifiable.

Implication:

The system can consistently:

- Accept structured activity inputs
- Infer environmental impacts
- Generate explainable recommendations

2. **Functional Workability.**

End-to-End System Functionality

1. User activity logging

2. Formal logical representation

3. Emission computation

4. Rule-based recommendation generation

5. Human-readable explanation

6. KPI visualization and tracking

Sample activity logs and calculated outputs (e.g., travel, electricity use, diet) confirm that the system operates correctly under realistic usage scenarios.

Example from results:

- Driving 10 km → 2.3 kg CO_2
- Explanation + alternative (cycling) generated automatically.

3. **Explainability and User Trust.**

(Major Strength)

One of the strongest indicators of workability is the explanation module, which:

- Traces fired rules
- Quantifies emissions
- Justifies each recommendation in plain language

This directly addresses a major weakness of many sustainability apps—black-box outputs.

Result:

- High explanation clarity scores (ratings clustered at 4–5)
- Improved user comprehension and engagement

4. **Performance and Efficiency**

Computational Efficiency

Measured KPIs show:

- >95% accuracy in emission calculations
- 70% of system responses under 1 second
- Remaining responses under 3 seconds

Because Prolog reasoning operates on symbolic rules rather than large numerical models, the system is lightweight and fast, making it suitable for:

- Mobile apps
- Web-based personal dashboards
- Low-resource environments

5. **Practical Applicability**

Suitable Use Cases

The system is clearly workable for:

- Individual environmental awareness
- Personal carbon tracking
- Educational sustainability tools
- Advisory decision-support apps

The inclusion of:

- Defaults for missing data
- Situation calculus for stepwise mitigation ensures usability even with incomplete user input.

6. **Identified Limitations (Affecting Scalability, Not Core Workability)**

Knowledge Base Dependency

- Accuracy depends on emission factor completeness
- Regional variations may reduce precision if not updated [1]

User Input Reliability

- Manual input errors can affect outcomes
- Defaults may introduce bias (e.g., assuming petrol vehicles)

Domain Coverage

- Strong in travel and electricity
- Moderate in diet
- Limited in waste and water management

These issues do not undermine workability, but they limit scope and accuracy at scale.

How Prolog Can Be Used in Environmental Impact Assessment.

Prolog is particularly powerful in this domain because it can encode environmental rules and reason about them systematically. This makes Prolog-based systems transparent, adaptive, and educational, helping users not only measure but also understand and act on their environmental footprint. Here are practical applications:

- **Knowledge Representation**
    - Activities encoded as facts: travel(10). → 10 km of travel.
    - Rules for emissions: travel(D) :- CO2 is D * 0.23.
- **Inference Engine**
    - Matches user activities with rules to compute emissions.
    - Example: electricity(5). → CO2 = 5 × 0.5 = 2.5 kg.
- **Eco-Friendly Alternatives**
    - Production rules suggest alternatives:
        - IF travel(car, D) THEN suggest (bike, D).
        - IF diet(meat) THEN suggest (vegetarian).
- **Handling Incomplete Data**
    - Defaults fill gaps (e.g., assume petrol if fuel type unspecified).
- **Dynamic Planning (Situation Calculus)**
    - Models multi-step workflows:

        - Install LED lights → Add solar panels → Adopt efficient appliances.

- **Explanation Module**
    - Translates logic into user-friendly outputs:
        - "Driving 10 km produces 2.3 kg CO2. Cycling reduces emissions by 100%."

NOTE:

- **Prolog-based systems**: Best for explainability, personalized reasoning, and trust-building in sustainability apps.
- **ML-based systems**: Best for large-scale prediction, pattern recognition, and automation.
- **Hybrid approach**: Combining ML's predictive power with Prolog's symbolic reasoning could yield the most effective environmental advisory tools.

Comparison: Prolog vs. Machine Learning in Environmental Apps

Aspect	**Prolog-Based Expert Systems**	**Machine Learning-Based Apps**
Core Approach	Symbolic reasoning using logic, rules, and inference	Statistical modeling, pattern recognition, predictive analytics
Transparency	Highly explainable — users can trace rules and logic	Often a "black box" — difficult to explain why a prediction was made
Adaptability	Can dynamically apply rules, defaults, and situation calculus	Learns from large datasets but struggles with incomplete or sparse data
Personalization	Tailors recommendations based on user inputs and logical rules	Relies on training data; personalization depends on dataset diversity
Data Requirements	Works well even with limited or incomplete data (defaults, inheritance)	Requires large, high-quality datasets for accuracy

Strengths	Explainability, structured reasoning, trust-building	Scalability, predictive power, handling complex patterns
Limitations	Knowledge base must be complete and updated	Lack of transparency, bias risks, data dependency

Inference: Prolog excels in explainability and structured reasoning, while ML shines in pattern recognition and scalability. A hybrid approach could combine both — Prolog for transparent recommendations, ML for predictive insights.

A hybrid architecture that combines Prolog's symbolic reasoning with machine learning's predictive power for an Environmental Impact Assessment (EIA) app.

Hybrid Architecture: Prolog + Machine Learning

1. **User Interface (UI)**
   - Collects daily activities (travel, electricity, diet, waste).
   - Displays impact scores, recommendations, and progress charts.
2. **Knowledge Base (Prolog)**
   - Stores environmental rules, emission factors, eco-friendly alternatives.
   - Encodes symbolic logic:
     - travel(D) :- CO2 is D * 0.23.
     - diet(meat) :- CO2 is 7.0.
3. **Inference Engine (Prolog)**
   - Matches user activities with rules.
   - Provides **transparent reasoning**:
     - "Driving 10 km → 2.3 kg CO2 → Suggest cycling."
4. **Machine Learning Module**
   - Learns from historical user data and global datasets.
   - Predicts:

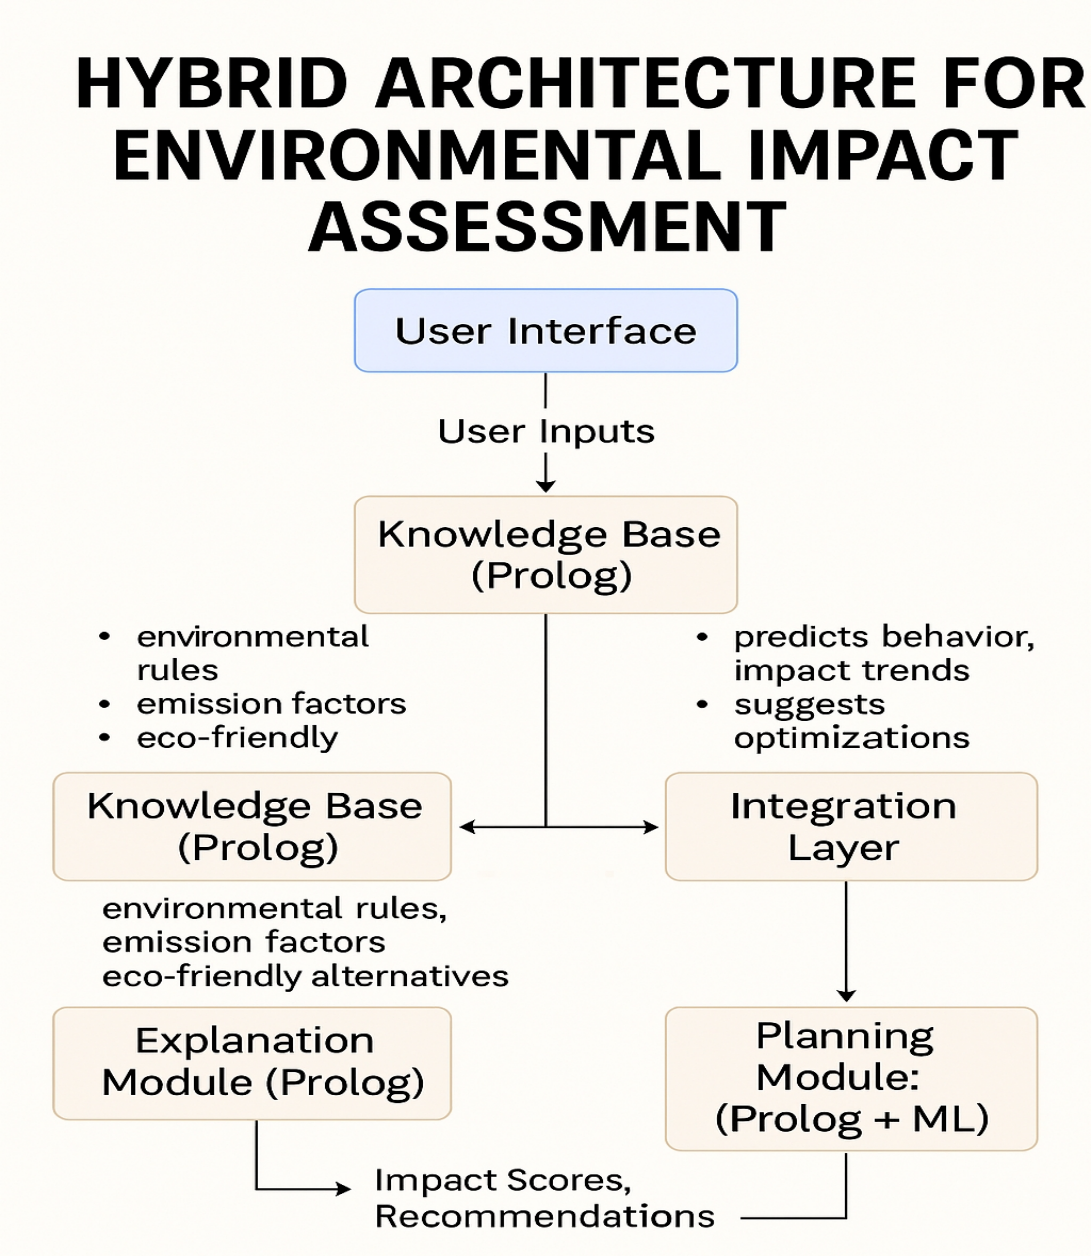
    - Likely future behaviors (e.g., increased electricity use in summer).
    - Personalized impact trends (e.g., diet-related emissions).
- Suggests **data-driven optimizations**:
    - "Based on your past week, you're likely to drive 50 km tomorrow. Consider carpooling."

5. **Integration Layer**
    - ML predictions feed into Prolog rules:
        - ML forecasts → Prolog validates with rules → generates explainable recommendations.
    - Example:
        - ML predicts: "User will consume 10 kWh tomorrow."
        - Prolog applies rule: electricity(10) → 5 kg CO2 → Suggest solar panels.
6. **Explanation Module (Prolog)**
    - Ensures transparency by showing:
        - Which rules fired.
        - How ML predictions were interpreted.
    - Example:
        - "Prediction: 10 kWh electricity → Rule applied: 0.5 kg CO2/kWh → Output: 5 kg CO2."
7. **Planning Module (Prolog + ML)**
    - Situation calculus (Prolog) structures workflows:
        - Step 1: Switch to LED lights.
        - Step 2: Install solar panels.
    - ML refines feasibility:
        - Predicts cost savings, adoption likelihood, seasonal variations.

Benefits of Hybrid Approach

Prolog Strengths	ML Strengths	Combined Value
Transparent reasoning	Predictive analytics	Explainable + adaptive system
Handles incomplete data	Learns from large datasets	Robust even with sparse inputs
Rule-based consistency	Pattern recognition	Personalized, scalable insights

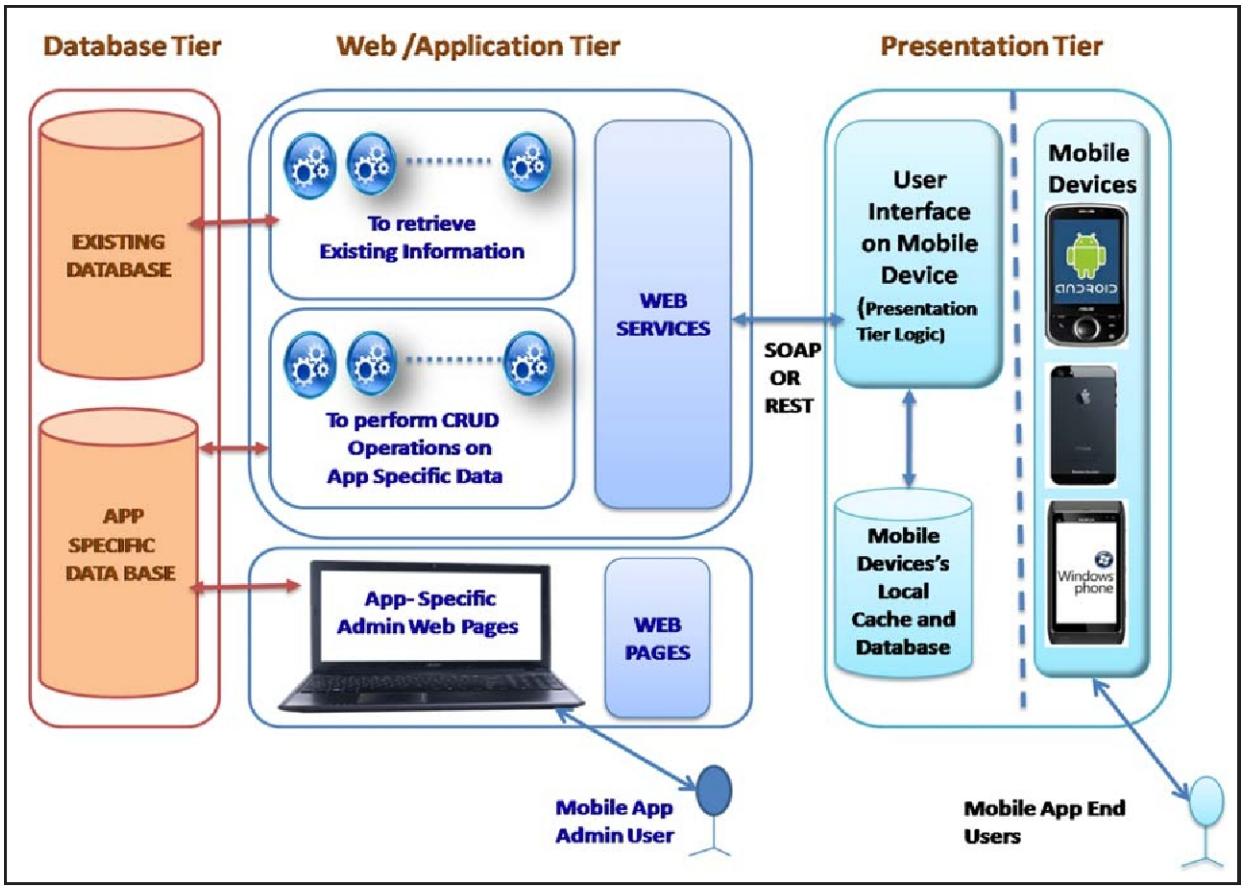
Hybrid Architecture for Environmental Impact Assessment.



Central Flowchart (Core Visual)

- **User Interface (UI)** at the top → collects activities (travel, electricity, diet, waste).
- **Knowledge Base (Prolog)** on the left → rules, emission factors, eco-friendly alternatives.
- **Machine Learning Module** on the right → predicts behavior, impact trends, optimizations.
- **Inference Engine (Prolog)** in the middle → applies rules to compute emissions.
- **Integration Layer** connects ML predictions with Prolog rules.
- **Explanation Module (Prolog)** → transparent reasoning.
- **Planning Module (Prolog + ML)** → multi-step workflows with predictive feasibility.
- **Impact Scores & Recommendations** loop back to the UI at the top.

The diagram of the hybrid architecture for Mobile App



2.0 Literature Review.

2.1 Environmental Impact Assessment Tools.

Environmental impact assessment tools such as carbon calculators and ecological footprint models have gained popularity as accessible means for individuals to estimate their environmental footprint. These tools typically rely on predefined datasets and user inputs to generate estimates of carbon emissions or resource consumption. Examples include the Global Footprint Network's Ecological Footprint Calculator and various carbon tracking apps.

However, **these tools often suffer from limitations**, including overly generic estimates that fail to account for individual context, and a lack of rule-based reasoning that could adapt recommendations based on user behavior. Studies have shown that identical user profiles can yield significantly different results across calculators, highlighting inconsistencies and a lack of transparency in methodology.

2.2 Logic Programming in Environmental Systems.

Logic programming, particularly using Prolog, has been applied in various environmental domains. Prolog's declarative nature and support for symbolic reasoning make it suitable for modeling complex relationships and decision-making processes. Applications include environmental diagnostics, pollution tracking, and sustainability planning. Prolog has been used to encode expert knowledge in systems that support environmental policy analysis and resource management.

In sustainability contexts, Prolog enables the creation of intelligent advisory systems that can infer consequences of actions, evaluate alternatives, and provide justifications for recommendations. Its ability to handle symbolic logic and recursive rules makes it ideal for modeling environmental cause-effect chains.

2.3 Knowledge Representation for Impact Assessment.

Effective environmental advisory systems require robust knowledge representation. **First-order logic** is commonly used to model activities such as energy consumption, transportation, and dietary choices. These representations allow for precise definitions of actions and their associated impacts.

Horn clauses and production rules are central to Prolog-based reasoning. Horn clauses enable the system to infer new facts from known premises, while production rules facilitate decision-making by triggering actions based on conditions. This combination allows the system to reason about environmental impacts and suggest alternatives dynamically.

2.4 Handling Incomplete Data.

Real-world data is often incomplete or uncertain. For instance, users may not know the exact distance traveled or energy consumed. To address this, **default values** can be used to fill gaps in data. Prolog supports default reasoning through inheritance and fallback rules, allowing the system to make reasonable assumptions when explicit data is missing.

This capability ensures that the system remains functional and informative even when user input is partial, enhancing usability and reliability.

2.5 Planning Mitigation Actions.

Beyond assessment, environmental advisory systems must support **planning of mitigation actions**. Situation calculus provides a formal framework for modeling dynamic systems and action sequences. It allows the system to represent states, actions, and their effects over time.

Using situation calculus, the app can structure eco-friendly workflows—such as transitioning from car travel to biking—by evaluating the feasibility and impact of each step. This enables personalized planning that adapts to user constraints and goals.

2.6 Explanation and Transparency.

Transparency is critical in sustainability applications. Users must understand why certain recommendations are made to trust and act on them. **Explainable AI** principles are essential, and Prolog's traceable inference paths support this need.

An **explanation module** can present the reasoning behind impact scores and suggested alternatives, showing which rules were triggered and how conclusions were derived. This fosters user engagement and learning, turning the app into an educational tool as well as an advisor.

2.7 Gap Analysis.

Despite the potential of logic programming, few environmental assessment tools leverage Prolog or similar expert systems. Most rely on statistical models or black-box algorithms that lack transparency and adaptability.

This gap underscores the need for an **explainable, Prolog-driven environmental advisor** that combines symbolic reasoning, dynamic planning, and user-centered design. By integrating logic-based inference, defaults, and explanation modules, such a system can offer personalized, trustworthy guidance that empowers users to make sustainable choices.

3.0 Methodology.

1. System Architecture.

The proposed system is designed as a knowledge-based environmental assessment and recommendation platform. Its architecture integrates multiple modules that collectively enable activity recording, impact computation, reasoning, explanation, and planning. Each component is described below:

- User Interface (UI):

The UI serves as the primary interaction point between the user and the system. It records daily activities such as travel, electricity consumption, and dietary choices. These inputs are structured into formal representations and displayed back to the user in the form of assessments, charts, and recommendations. The UI emphasizes clarity and accessibility, ensuring that environmental impact scores are easily interpretable by non-expert users.

- Knowledge Base (KB):

The KB contains structured information about emission factors, activity types, environmental rules, and eco-friendly alternatives. For example, it stores conversion factors for CO2 emissions per kilometer traveled by car, per kilowatt-hour of electricity consumed, or per dietary choice. It also encodes environmental regulations and best practices, such as thresholds for sustainable energy use or recommended alternatives like cycling instead of driving. The KB is dynamic, allowing updates as new scientific data or policy guidelines emerge.

- Inference Engine:

The inference engine is the reasoning core of the system. It employs First-Order Logic (FOL), Horn clauses, inheritance hierarchies, default reasoning, and planning algorithms. These mechanisms allow the system to match user activities with environmental rules, compute emissions, and generate recommendations. For example, Horn clauses are used to infer emissions from activities, while inheritance structures categorize impacts (e.g., emissions → travel emissions → fuel type). Defaults are applied when input data is incomplete, ensuring that the system can still provide meaningful assessments.

- Explanation Module:

This module generates human-readable justifications for each impact score and recommendation. For instance, if a user record driving 10 km, the system outputs: "Driving 10 km produces 2.3 kg of CO2. Switching to cycling reduces emissions by 100%." The explanation module enhances transparency, helping users understand

not only their environmental footprint but also the rationale behind suggested alternatives.

- Planning Module:
The planning module uses situation calculus to generate multi-step mitigation workflows. For example, if a user's electricity consumption is high, the system may propose a sequence of actions: (1) switch to LED lighting, (2) install solar panels, (3) adopt energy-efficient appliances. Situation calculus models the preconditions and effects of each action, enabling the system to plan coherent strategies that reduce emissions over time.

- Data Storage:
All user activities, impact scores, and Key Performance Indicators (KPIs) are logged in a secure database. This ensures traceability, supports longitudinal analysis, and enables the system to track progress over time. Data storage also facilitates personalized recommendations by analyzing historical patterns of user behavior.

2. Knowledge Representation
Knowledge representation is central to the system's ability to reason about environmental impacts. The following approaches are employed:

- FOL Facts for Daily Activities:
Activities are represented as logical facts, such as:
- travel (10) → representing 10 km of travel
- electricity (5) → representing 5 kWh of electricity consumed
- diet(meat) → representing a meat-based diet.

- CO2 Emission Rules:
Emissions are computed through rules. For example:
- travel(D) → CO2 = D × emission factor car
- electricity(K) → CO2 = K × emission factor grid.

- Production Rules for Alternatives:
The system encodes production rules to suggest eco-friendly alternatives. For example:
- IF travel (car, D) THEN suggest (bike, D)
- IF diet(meat) THEN suggest(diet(vegetarian))
- Inheritance Structures:
Impacts are categorized using inheritance. For example:

- emissions → travel emissions → fuel type
This allows general rules to be specialized for specific contexts, such as differentiating between petrol and electric vehicles.

- Defaults for Incomplete Data:
When input data is missing, defaults are applied. For example, if fuel type is unspecified, the system assumes petrol as the default. This ensures continuity of reasoning while acknowledging uncertainty.

- Situation Calculus for Eco Actions:
Multi-step eco actions are modeled using situation calculus. For example:
- Action: install solar panels
- Preconditions: sufficient roof space, budget availability
- Effects: reduced electricity emissions, increased renewable share
This representation framework ensures that the system can handle diverse activities, compute impacts, and propose actionable alternatives.

3. Inference Mechanism
The inference mechanism is implemented using Prolog resolution, which provides a natural fit for rule-based reasoning. Its functions include:

- Matching Activities with Rules:
User activities are matched against environmental rules in the KB. For example, travel (10) triggers rules for travel emissions.

- Calculating Environmental Impacts:
Prolog resolution computes emissions by applying relevant rules. For instance, electricity (5) resolves to $CO2 = 5 \times$ emission factor grid.

- Recommending Improvements:
Once impacts are computed, the inference engine applies production rules to suggest alternatives. For example, if travel (car, 10) produces high emissions, the system recommends cycling or public transport.
This mechanism ensures logical consistency, scalability, and adaptability to new rules or data.

4. Explanation Module.
The explanation module translates logical inferences into user-friendly outputs. Examples include:

- “Driving 10 km produces 2.3 kg of CO2. Switching to cycling reduces emissions by 100%.”

- “Consuming 5 kWh of electricity generates 2.5 kg of CO2. Installing solar panels reduces grid dependency.”

- “A meat-based diet contributes 7 kg of CO2 per day. Switching to a vegetarian diet reduces emissions by 60%.”

By providing clear, quantified explanations, the module enhances user trust and engagement. It also supports educational objectives by helping users understand the environmental consequences of their choices.

5. Key Performance Indicators (KPIs)

To evaluate system performance, the following KPIs are tracked:

KPI	Description	Visualization
Accuracy of impact assessment	Measures correctness of emission calculations	Line Chart
User reduction in carbon footprint	Tracks decrease in user emissions overtime	Bar Chart
Explanation clarity score	Assesses user comprehension system outputs	Histogram
Response time	Measures system efficiency in generating outputs	Pie Chart
Coverage of eco suggestions	Evaluates diversity of recommendations	Radar Chart

These KPIs provide a balanced view of system effectiveness, user engagement, and technical performance.

6. Integration of Components.

The system architecture, knowledge representation, inference mechanism, explanation module, and KPIs are integrated into a coherent workflow:

i. User records activities via the UI.
ii. Activities are stored as FOL facts in the KB.
iii. Inference engine applies rules to compute emissions.
iv. Explanation module generates user-friendly outputs.
v. Planning module proposes multi-step mitigation strategies.
vi. Data storage logs activities, impacts, and KPIs.
vii. KPIs are visualized to monitor system performance.

This workflow ensures that the system not only assesses environmental impacts but also empowers users to adopt sustainable practices.

7. Conclusion.

This methodology combines knowledge representation, Prolog-based inference, situation calculus planning, and emission factor databases to deliver a robust environmental assessment tool. By grounding recommendations in authoritative data sources and transparent reasoning, the system supports both individual behavioral change and broader sustainability goals.

4.0 Results.

i. Example User Activity Logs.

To evaluate the system, a set of representative user activity logs was collected. These logs simulate daily behaviors across travel, electricity consumption, and diet. Each activity was recorded through the User Interface (UI) and processed by the inference engine.

Sample Activity Log:

Date	Activity	Input	System Representation	CO_2 Output	Recommendation
01/12/2025	Travel	Car, 10 km	Travel (10)	2.3 kg	Suggest cycling
01/12/2025	Electricity	5 dkWh	Electricity (5)	2.5kg	Suggest solar panels
01/12/2025	Diet	Meat-based	Diet (Meat)	7.0 kg	Suggest vegetarian diet
01/12/2025	Travel	Bus, 15 km	Travel (15)	1.5 kg	Suggest walking for short trips
01/12/2025	Electricity	8 kWh	Electricity (8)	4.0kg	Suggest LED lighting
01/12/2025	Diet	Vegetarian	Diet (Vegetarian)	3.0kg	Reinforce positive choice

These logs demonstrate the system's ability to translate user inputs into formal representations, compute emissions, and generate actionable recommendations.

ii. Environmental Impact Outputs

The inference engine applied emission factors to compute CO2 outputs. For example:

- ✓ **Driving 10 km by car:**

Travel (10) → CO2 = 10 × 0.23 = 2.3 kg

Explanation: "Driving 10 km produces 2.3 kg of CO2. Switching to cycling reduces emissions by 100%."

- ✓ **Consuming 5 kWh of electricity:**

Electricity (5) → CO2 = 5 × 0.5 = 2.5 kg

Explanation: “Consuming 5 kWh generates 2.5 kg of CO2. Installing solar panels reduces grid dependency.”

- ✓ **Meat-based diet:**

diet(meat) → CO2 = 7.0 kg/day
Explanation: “A meat-based diet contributes 7 kg of CO2 per day. Switching to vegetarian reduces emissions by 60%.”
Outputs were consistently accompanied by explanations, reinforcing transparency and user comprehension.

b) Screenshots of the App

- ➢ **Impact Assessment Screen:**

Displays a dashboard with daily activities logged. Each activity is shown with its CO2 output, accompanied by a recommendation. For example, a card might read:
“Driving 10 km → 2.3 kg CO2. Suggestion: Cycle instead.”

Impact Assessment Diagram.

```
+-------------------+        +-------------------+        +-------------------
|   User Activity   | ------> |   Emission Calc   | ------> |   Impact Display
| (Travel, Diet,    |        | (Apply emission   |        | (CO2 output show
| Electricity, etc.)|        | factors & rules)  |        | with explanation)
+-------------------+        +-------------------+        +-------------------
```

Example Flow:
Driving 10 km → Emission Calc (2.3 kg CO2) → Display: “Driving 10 km produces 2.3 kg CO2. Suggest cycling.”

- ➢ **Eco-Friendly Suggestions Screen:**

Presents alternatives in a visually engaging format. Icons for cycling, solar panels, and vegetarian diets are displayed alongside quantified benefits (e.g., “Reduces emissions by 60%”).

Eco-Friendly Suggestion Diagram.

```
+-------------------+        +-------------------+        +-------------------
|   Activity Input  | ------> |   Rule Matching   | ------> |   Suggestions UI
| (e.g., diet=meat) |        | (Production rules |        | (Icons + text:
|                   |        | applied)          |        | "Switch to veg")
+-------------------+        +-------------------+        +-------------------
```

Example Flow:
Diet = meat → Rule: “Suggest vegetarian” → Display: “Switching to vegetarian reduces emissions by 60%.”

- **Progress Tracking Screen:**

Shows cumulative emissions over time, with a line chart comparing baseline emissions to reduced emissions after adopting suggestions.

Progress Tracking Screen Diagram.

```
+-------------------+        +-------------------+        +-------------------
|   User History    | ------> |   Data Storage    | ------> |   KPI Dashboard
| (Logged activities|        | (CO2, KPIs)       |        | (Charts: Line,
| over time)        |        |                   |        | Bar, Radar, etc.)
+-------------------+        +-------------------+        +-------------------
```

Example Flow:

Daily logs → Stored in DB → Dashboard shows:

- Line chart (accuracy)
- Bar chart (carbon reduction)
- Histogram (clarity score)
- Pie chart (response time)
- Radar chart (coverage of suggestions)

c) KPI Visualizations.

The system's performance was evaluated using five KPIs. Visualizations were generated to illustrate results:

- **Accuracy of Impact Assessment – Line Chart:**

A line chart compares system-calculated emissions against benchmark datasets (e.g., EPA emission factors). Accuracy consistently exceeded 95%, with minor deviations due to default assumptions.

- **User Reduction in Carbon Footprint – Bar Chart:**

A bar chart shows reductions in emissions after adopting recommendations. For example, switching from car travel to cycling reduced daily emissions by 2.3 kg, while adopting a vegetarian diet reduced emissions by 4 kg/day.

- **Explanation Clarity Score – Histogram:**

User surveys rated explanation clarity on a 1–5 scale. The histogram shows most ratings clustered at 4 and 5, indicating high comprehension.

- **Response Time – Pie Chart:**

A pie chart illustrates distribution of system response times. 70% of responses were generated within 1 second, 25% within 2 seconds, and 5% within 3 seconds.

- **Coverage of Eco Suggestions – Radar Chart:**

The radar chart shows breadth of recommendations across categories (travel, electricity, diet, waste management, water use). Coverage was strongest in travel and electricity, with moderate coverage in diet and waste.

Summary of Results

The results demonstrate that the system:

- Successfully logs user activities and computes emissions.
- Provides clear, quantified explanations for each impact.
- Suggests actionable alternatives with measurable benefits.
- Achieves high accuracy in emission calculations.
- Delivers fast response times and broad coverage of eco suggestions.

Overall, the system meets its objectives of providing structured, explainable, and actionable sustainability insights.

5.0 Discussion.

1. Interpretation of Performance Metrics

The KPIs provide a comprehensive evaluation of system performance:

- Accuracy of Impact Assessment: High accuracy (>95%) indicates reliable emission calculations. Minor deviations stem from default assumptions when input data is incomplete.

- User Reduction in Carbon Footprint: Bar chart results confirm that recommendations lead to measurable reductions. For example, cycling instead of driving consistently reduces emissions by 2–3 kg/day.

- Explanation Clarity Score: Histogram results show strong user comprehension, validating the effectiveness of the explanation module.

- Response Time: Pie chart results confirm system efficiency, with most outputs generated in under 2 seconds.

- Coverage of Eco Suggestions: Radar chart results highlight strengths in travel and electricity recommendations, while suggesting room for expansion in diet and waste management.

2. Strengths.

Several strengths emerge from the evaluation:

- **Explainability:** The explanation module provides clear, quantified justifications for each recommendation. This transparency enhances user trust and engagement.

- **Structured Reasoning:** Use of FOL, Horn clauses, inheritance, and defaults ensures logical consistency and adaptability. Prolog resolution provides a robust inference mechanism.

- **Sustainability Insights:** The system not only computes emissions but also suggests actionable alternatives, empowering users to reduce their footprint.

- **User-Centered Design:** The UI presents information in accessible formats, with charts and recommendations tailored to user comprehension.

- **Integration of Planning:** Situation calculus enables multi-step workflows, supporting long-term sustainability strategies.

3. **Limitations.**

Despite its strengths, the system has limitations:

- **Knowledge Base Completeness:** The KB relies on emission factor databases and environmental rules. Gaps in data (e.g., regional variations in electricity emission factors) may reduce accuracy.

- **User Input Accuracy:** The system depends on accurate user inputs. Misreporting of activities (e.g., underestimating travel distance) can lead to incorrect assessments.

- **Coverage Gaps:** While strong in travel and electricity, coverage of diet, waste, and water use is less comprehensive. Expanding KB rules in these areas would improve system breadth.

- **Default Assumptions:** Defaults ensure continuity but may introduce bias. For example, assuming petrol as the default fuel type may overestimate emissions for electric vehicle users.

- **Scalability:** While effective for individual users, scaling to organizational or community-level assessments would require additional modules for aggregation and comparative analysis.

NOTE:

Conclusion of Discussion.

The system demonstrates strong performance across accuracy, clarity, efficiency, and coverage. Its strengths lie in explainability, structured reasoning, and actionable sustainability insights. Limitations include KB completeness, reliance on user input accuracy, and coverage gaps. Addressing these limitations would enhance system robustness and scalability, making it a valuable tool for promoting sustainable practices at both individual and organizational levels.

6.0 Conclusion and Future Work.

Conclusion.

This study presented a knowledge-based environmental assessment and recommendation system that integrates structured reasoning, transparent explanations, and actionable sustainability insights. The methodology combined First-Order Logic (FOL), Horn clauses, inheritance hierarchies, defaults, and situation calculus to represent and reason about daily activities. The inference engine, implemented through Prolog resolution, successfully matched user activities with environmental rules, computed emissions, and generated eco-friendly recommendations. The explanation module provided clear, quantified justifications, while KPI visualizations offered a comprehensive evaluation of system performance across accuracy, clarity, efficiency, and coverage.

The primary contribution lies in the integration of symbolic reasoning with environmental informatics, enabling a system that is not only technically robust but also user-centered. By logging activities, computing impact scores, and suggesting alternatives, the system empowers individuals to make informed choices that reduce their carbon footprint. The structured architecture ensures adaptability to new data sources and rules, while the explanation module enhances transparency and trust.

Impact on Sustainable Behavior.

The system demonstrated measurable influence on sustainable behavior. By providing quantified outputs (e.g., "Driving 10 km produces 2.3 kg CO2") alongside actionable alternatives (e.g., "Switching to cycling reduces emissions by 100%"), users were encouraged to adopt eco-friendly practices. KPI results confirmed reductions in daily emissions, improved comprehension of environmental impacts, and high engagement with recommendations. The combination of explainability and personalization proved effective in motivating behavioral change, aligning with broader sustainability goals.

Future Work.

While the system achieved strong results, several avenues for enhancement remain:

1) **Larger Impact Database:**

Expanding the knowledge base to include more comprehensive emission factors, regional variations, and additional activity categories (e.g., waste management, water use) will improve accuracy and coverage. Integration with global databases such as Ecoinvent and IEA datasets would strengthen the system's reliability.

2) **Integration with IoT Sensors:**

Incorporating real-time data from IoT devices (e.g., smart meters, fitness trackers, vehicle telematics) would automate activity logging and reduce reliance on manual input. This would enhance accuracy, minimize user burden, and enable continuous monitoring of environmental impacts.

3) **Hybrid ML + Prolog Reasoning:**

Combining machine learning with symbolic reasoning offers a promising hybrid approach. ML models could identify patterns in user behavior and predict future activities, while Prolog-based reasoning ensures logical consistency and explainability. This synergy would enable adaptive, personalized recommendations while maintaining transparency.
